### ABSTRACT

Metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions, respectively, induced bacteriolytic mechanism has been elucidated against *S. aureus* and *E. coli*. Bacteriolytic mechanism for Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions, respectively, induced *S. aureus* is clarified that bacteriolysis and destruction of *S. aureus* PGN cell wall occur by inhibition of PGN elongation through metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions-induced PGN inhibitory transglycosylase (TG) and transpeptidase (TP) syntheses (TG for Zn<sup>2+</sup>) and PGN activated major autolysin of amidase. The other, bacteriolytic mechanism for Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions, respectively, induced *E. coli* is found that bacteriolysis and destruction of *E. coli* cell wall occur by disruption of *E. coli* outer membrane (OM) structure with OM lipoprotein-endopeptidase activation, and by inhibition of PGN elongation through inhibitory TG and TP syntheses (TG for Zn<sup>2+</sup>) and PGN activated major autolysins.

Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions-induced ROS generation of O<sub>2</sub>- and H<sub>2</sub> O<sub>2</sub> and ROS-mediated oxidative stress in bacterial cell lead to killing by stress damage for silver ions, cell membrane damages due to high reactive •OH and OH<sup>-</sup> are formed by Haber-Weiss and Fenton reactions for Cu<sup>2+</sup> ions, and DNA molecular damage for Zn<sup>2+</sup> ions.

### INTRODUCTION

High antibacterial activities for Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ion solutions have the processes of bacteriolyses and destructions of bacterial cell walls against Staphylococcus aureus (S. aureus) peptidoglycan (PGN) and Escherichia coli (E. coli) outer membrane cell walls. Ag<sup>+</sup>, Cu<sup>2+</sup>. Zn<sup>2+</sup> ion solutions having very high antibacterial abilities call attention to potential treatments such as the prevention of serious diseases, and restriction of viral infection. Anti-bacterial activity of silver(I) ions depends on bacteriolysis and destruction of bacterial cell walls, in which silver ions inhibit PGN elongation and PGN biosynthesis, and enhance PGN autolysin activation [1]. Especially, the interaction of silver ions with Escherichia coli (E. coli) used as a model microorganism is characterized by energy-filtering transmission electron microscopy (EFTEM) that the outer membrane and the interior cell membrane with cytoplasmic protein were destructed by silver ions [2], in which bacterial killing of silver ions is shown to have a strong highest function for the destructions of E. coli outer membrane lipoprotein and inner membrane protein.

Copper ions destroy the bacterial cell wall, which becomes thick and coarse, the cytoplasm is then degraded and disappears, leading finally to cell death. The antibacterial mechanism is attributed mainly to the strong adsorption of copper ions to bacterial cells, which imparts antibacterial efficacy in a concentration-dependent manner [3]. The bacteriolytic mechanisms by copper (I) ions had been revealed that bacteriolysis of S. aureus PGN cell wall by Cu2+ ions is ascribed to the inhibition of PGN elongation due to the damages of PGN biosynthesis of transglycosylase (TG) and transpeptidase (TP), and the Cu<sup>2+</sup> ions-induced activated PGN autolysins, whereas bacteriolysis of E. coli outer membrane cell wall by Cu<sup>2+</sup> ions is attributed to the destruction of outer membrane structure and the inhibition of PGN elongation due to the damage of PGN biosynthesis TP and the activations of PGN autolysins [4].

Zn<sup>2+</sup> ions can be internalized into the bacterial cell and disrupt the enzymatic system. ROS production (causing the destruction of cellular components such as DNA, proteins and lipids):  $O_2^-$  and  $HO_2^-$  do not penetrate the membrane, but direct contact causes damage, and  $H_2O_2$  is internalized. Internalization within the bacteria cell and direct contact cause damage such as the loss of cellular integrity [5]. Zinc ions-induced anti-bacterial mechanism also may be clarified. It had appeared that the anti-bacterial effects had the order of Zn<sup>2+</sup> > Cu<sup>2+</sup> > Ag<sup>+</sup> > Al<sup>3+</sup> in metallic ion concentration 100 mL

of the sulfate solution under the halo inhibitory tests, in which Zn<sup>2+</sup> ion indicated to be the highest effect in the sulfates [6].

In this semi-review article, silver(I)-, copper(II)-, zinc(II)-, respectively, induced bacteriolytic functions of inhibition or activation of *E. coli* outer-membrane lipoprotein, PGN elongation by bacterial PGN inhibitory synthesis, and PGN activated major autolysins are investigated against *S. aureus* and *E. coli*. Subsequently, insights into bacteriolytic mechanisms for silver, copper, and zinc ions-induced bacteriolyses and destructions of bacterial cell wall are elucidated from relating metallic ions-induced bacteriolytic denaturation of outer-membrane lipoprotein (Braun's lipoprotein), bacterial PGN elongation, syntheses, and autolysins.

Bacterial surface molecular structures, *S. aureus* PGN cell walls, *E. coli* OM lipoprotein, PGN syntheses, PGN autolysins, and the action sites of *S. aureus* PGN cell walls, *E. coli* OM lipoprotein, PGN syntheses TG/TP, and PGN autolysins against *S. aureus* and *E. coli* 

Figure 1 (a), (b) show *S. aureus* and *E. coli* surface molecular structures, *E. coli* OM lipoprotein, bacterial PGN syntheses TG/ TP, PGN autolysins, and the action sites of *E. coli* OM lipoprotein Endopeptidase, PGN syntheses TG/TP, and PGN autolysins against *S. aureus* and *E. coli*. Table 1 is represented summarily *E. coli* OM lipoprotein degrading enzyme, and bacterial PGN syntheses and autolysins against *S. aureus* and *E. coli* that *E. coli* OM lipoprotein-endopeptidase, these PGN syntheses, and autolysins sites are shown in Figure 1 (a), (b). Bacterial PGN structures of both Gram-positive and Gram-negative bacteria comprise repeating disaccharide backbones of N-acetylglucosamine (NAG) and  $\beta$ -(1-4)-N-acetylmuramic acid (NAM) that are crosslinked by peptide stem chains attached to the NAM residues [7].

S. aureus surface layer consists of teichoic acids, lipoteichoic acids, and thick PGN cell wall, in which the molecular structure of S. aureus PGN cell wall and the action sites of synthesis TG/TP enzymes and PGN forth autolysins, as shown in Figure 1(a). For Staphylococcus aureus (S. aureus) PGN layer, there are biosynthesis TG/TP and forth autolysins of N-acetylmuramidase and N-acetylglucosamidase, N-acetylmuramidase-L-alanine amidase and PGN chain crosslinkage DD-endopeptidase. The S. aureus killing mechanism was more likely due to activation autolysins along with minimum membrane disruption [8]. In these autolysins, zincdependent PGN major autolysin of amidases chiefly may be enhanced induced anti-bacterial activities. The other, E. coli

cell wall consists of lipid A, lipopolysaccharide, porin proteins, outer membrane of lipoprotein, and thinner 2-7 nm PGN layer in 30-70 nm periplasmic space [9].

E. coli cell wall is constituted of lipopolysaccharide (LPS), lipoproteins (LPT), and PGN, thinner layer within periplasmic space. The first permeability barrier of zinc ions in the E. coli cell wall is highly anionic LPS with hydrophobic lipid A, core polysaccharide, O-polysaccharide, in which zinc ions may be possible for the inhibition of LPS biosynthesis, owing to that promotes formation of metal-rich precipitates in a cell surface [10]. E. coli Braun's lipoprotein (BLP) of outer-membrane (OM) lipoprotein that BLP is anchored in the OM via a lipidated N-terminus, whereas the C-terminus is covalently attached to the peptide chain of PGN and that BLP exists in PGN-bound and PGN-unbound states, the length of BLP has a direct influence on the distance between the peptidoglycan layer and the outer membrane of E. coli in Figure 1(b) [11]. Penicillin binding protein4 (PBP4) localizes specifically at midcell as part of the division machinery that PBP4 is a periplasmic endopeptidase with a C-terminal amphipathic alpha-helix that associates with membranes and has three domains

[12]. Despite its conservation throughout evolution among pathogenic and non- pathogenic bacteria, OmpA interacts with specific receptors for initiating pathogenesis in some Gram-negative infections [13].

The gram-negative bacterial cell envelope is made up of an OM, an inner membrane (IM) that surrounds the cytoplasm, and a periplasmic space that in several bacteria, including E. coli, the OM is tethered to PGN by an abundant OM lipoprotein, Lpp (or Braun's lipoprotein), that functions to maintain the structural and functional integrity of the cell envelope. Since its discovery, Lpp has been studied extensively, and although L,D-transpeptidases, the enzymes that catalyze the formation of Lpp-PGN linkages, have been earlier identified, it is not known how these linkages are modulated. Recently, LdtF is identified as an endopeptidase that cleaves the Lpp-PGN cross-links and as a glycine-specific carboxypeptidase [14]. For Escherichia coli (E. coli) cell wall, there are endopeptidase and aminopeptidase of degrading enzyme at lipoprotein of N- and C-terminals, and amidase, peptidase, and caboxypeptidase at thin PGN layer in periplasmic space [15].

### Insight into silver(I) ions-induced bacteriolysis function against *S. aureus* and *E. coli*

### (1) Silver(I) ions induced PGN cell wall inhibitory synthesis TG/TP against *S. aureus*

In silver nitrate solution,  $AgNO_3$  is dissociated into aqua silver ion  $[Ag (H_2O)_2]^+$  and nitrate ion  $(NO_3)^-$ , aqua silver ions are liable to be bound to ligand L having negative charge. The nitrate ion has bactericidal inactivity. For silver nitrate in solution is

 $AgNO_{3} + 2H_{2}O = [Ag(H_{2}O)_{2}] + (NO_{3})$  $[Ag(H_{2}O)_{2}]^{+} + L - = Ag(H_{2}O)_{2}L$  $Ag(H_{2}O)_{2}L = AgL + 2H_{2}O$ 

The released Ag+ ions from AgNO3 solution penetrate into bacterial cells, can inhibit the growth of Gram-positive *B. subtilis* bacterium which exerts toxicity by damaging cellular membrane, degrading chromosomal DNA, lowering reductase activity, and reducing protein expression. Wall teichoic acids are spatial regulators of PGN crosslinking biosynthesis of transpeptidase (TP), and silver ions could inhibit both transglycosylase (TG) and TP enzymes of the PGN that Ag<sup>+</sup>-induced bacteria may inactivate PGN synthesis TG and TP [16]. Silver ions can inhibit both TG and TP enzymes of the PGN that Ag<sup>+</sup>-induced bacteria inactivate PGN synthesis transglycosylase TG and transpeptidase TP [17,18]. In proteins, the coordination is limited by His, Cys, Glu, and sulfur donors from the side chains of a few amino acids.

### (2) Silver ions induced activation of PGN major autolysins against *S. aureus* cell wall

For the sake of growth of S. aureus thick PGN layer cell wall,

there is necessarily required for the adequate balance between PGN synthesis and PGN autolysin. When the balance was broken to be imbalanced, bacteriolysis and destruction of the cell wall should occur. Hence, it became apparent that bacteriolysis of *S. aureus* PGN cell wall by Ag<sup>+</sup> ions is caused by inhibition of PGN elongation due to inactivation of PGN TG or TP and enhancement of activation of PGN autolysins of amidases, in which silver ions enhance activation of PGN autolysins of amidases [19]. Thus, Ag<sup>+</sup> ions activate PGN major autolysins of bacteriolysis of *S. aureus* PGN cell wall, in which wall teichoic acids control PGN synthesis cross-linking TP, is due to the inhibition of PGN elongation by enhancing the activities of PGN autolysins; amidase AmiA and AmiE, and PGN hydrolase Lysostaphin-like endopeptidase (Glycine-Glycine bond cleavage).

Accordingly, Ag<sup>+</sup> ions-induced bacteriolytic mechanism against *S. aureus* has been found that bacteriolysis and destruction of the PGN cell wall occur by Ag<sup>+</sup> ions-induced inhibition of PGN elongation through inhibitive TG/TP and PGN activated major autolysin.

## (3) Silver ions induced disruption of *E. coli* outer membrane structure by hydrolases of lipoproteins at C- and N-terminals

*E. coli* outer-membrane lipoprotein structure had been observed to be destructed by silver ions [2], in which silver ion is shown to have interaction with protein Braun lipoprotein. Silver nitrate has interaction with protein Braun lipoprotein and is capable of making interaction with many proteins by that bioinformatic interaction of silver nitrate with Braun lipoprotein [20].

It is unclear whether both Aminopeptidase and Endopeptidase (or *L,D-transpeptidase, LdtF*) of lipoprotein at C- and N-terminals are simultaneously activated by Ag<sup>+</sup> ions. However, outer membrane may be considered to be disrupted probably by predominant activation of lipoprotein-*endopeptidase*. There is no data about Ag-lipoprotein aminopeptidase, *LdtF* enzyme interactions, hence, whether Ag<sup>+</sup> ions react with *endopeptidase* enzyme or not [14].

Silver inhibits outer membrane protein (OMP) that the molecular mechanism of the antibacterial activity of silver and molecular changes in bacterial cells strongly depend on the physical and chemical properties of the tested silver nanoformulation form (SNF) [21]. A silver-binding peptide, AgBP2, was identified from a combinatorial display library and fused to the C terminus of the *E. coli* maltose-binding protein (MBP) to yield a silver-binding protein exhibiting nanomolar affinity for the metal [22].

Silver ions may be accumulated and damaged in *E. coli* PGN synthetic enzyme of silver protein *endopeptidase* in periplasmic space, in which the silver ions are spent to the activation of bacteriolysis of the cell wall and efflux activity to extracellular cell. Then, endopeptidase (L,D-transpeptidase, LdtF) of lipoprotein endopeptidase is degradative by Ag<sup>+</sup> binding proteins.

(4) Silver ions-induced activation of PGN major autolysins of amidase, peptidase, and carboxypeptidase against *E. coli* Silver ions inactivate TP of endopeptidase by because of destructive observation of bacterial cell walls. Silver ions could activate *E. coli* PGN autolysins of amidase, peptidase, Carboxypeptidase, such as silver depending PGN autolysin, AmiC, AmiD, Muramidase, Amino acid amidase, Carboxypeptidase A, Bacteriolysis and destruction for *E. coli* cell wall also are considered to be due to the damage of LPS synthesis, destructing of outer membrane structure by degrading of lipoprotein at C-, N-terminals, and to be owing to inhibition of PGN formations by inactivation of carboxypeptidase and TP-endopeptidase, and activities of PGN autolysins of amidase, peptidase, and carboxypeptidase.

Thus, bacteriolytic mechanism for Ag<sup>+</sup> ions against *E. coli* has been found that silver ions induced bacteriolysis and destruction of *E. coli* cell wall are caused by the disruption of outer membrane structure owing to the activation of endopeptidase of lipoprotein at C-, and N-terminals, and by the inhibition of PGN elongation through the damage of PGN synthetic TG/TP enzyme and PGN major activated autolysins

of Amidase, Peptidase, and Carboxypeptidase in silver-protein amidases in periplasmic space. Specially, the inhibition of PGN elongation occurs by silver ion induced activities of PGN hydrolases and autolysins.

### (5) Silver(I) ions induced ROS generation in *S. aueus* and *E. coli*

For the penetration of Ag<sup>+</sup> ions to *S. aureus* PGN cell wall, the ROS production such as superoxide anion radical  $O_2^{-}$ , hydroxyl radical 'OH, hydrogen peroxide  $H_2O_2$  occurred from superoxide radical  $O_2^{-}$  molecular.  $O_2^{-}$  and  $H_2O_2$  permeate into membrane and cytoplasm, and then, DNA molecular is damaged by oxidative stress [23]. Silver ions react with -SH, and H<sup>+</sup> in *E. coli* that free radicals  $O_2^{-}$ , OH<sup>-</sup>, OH and  $H_2O_2$  are formed as follows:

 $O_2 + e \rightarrow O^- \qquad 2O^- + 2H^+ \rightarrow H_2O_2 + O_2$  $O^- + H_2O_2 \rightarrow OH^- + OH^- + OH^- + O_2^-$ 

In cell wall, reacting with polyunsaturated fatty acids:

 $\mathsf{LH} + \mathsf{OH}^{,} \to \mathsf{L}^{,} + \mathsf{HOH}$ 

 $L^{*} + O2 \rightarrow LOO^{*} LH + LOO^{*} \rightarrow L^{*} + LOOH$ 

Thus, Ag<sup>+</sup>-containing peptidoglycan recognition proteins (PGRPs) induce ROS production of  $H_2O_2$ ,  $O^-$ , HO, and then the ROS occur oxidative stress, and killing by stress damage [24].

Insight into copper(II) ions-induced bacteriolysis function against *S. aureus* and *E. coli* 

### (1) Copper(II) ions-induced *S. aureus* with coordinated limited ligand

Copper is redox-inert and has only one valence state of Cu(II). In proteins, the coordination is limited by His, Cys, Glu, and sulfur donors from the side chains of a few amino acids. In copper sulfate solution,  $CuSO_4$  is dissociated into aqua Cu ion  $[Cu (H_2O)_6]^{2+}$  and sulfuric ion(SO) <sup>-</sup> aqua Cu ions are liable to be bound to ligand L having negative charge. The sulfuric ion has bactericidal inactivity

 $Cu(NO_3)_2 + 6H_2O = [Cu(H_2O)_6]^{2+} + 2(NO_3)^{-1}$ 

 $[Cu(H_2O)_6]^{2+} + 2L - = CuL_2 + 6H_2O$ 

### (2) Inhibition of polymerization of glycan chains bonding and cross-linking of side peptide

Cu<sup>2+</sup> ions may inhibit polymerization of glycan chains, forming

copper complex in which is partial action sites of glycan saccharide chains [4]. L is coordinated molecular.

#### $Cu^{2+} + LH \rightarrow CuL^+ + H^+$ $CuL^+ + LH \rightarrow CuL_2 + H^+$

Copper-complexes on saccharide chains may be,

#### Glycan chaine; -NAG-(NAM-Cu-2O-2N-NAG)-NAM-.

The other, Cu<sup>2+</sup> ions may inhibit cross-linked reaction by peptide copper complex formation bonding to sidepeptide chains.

### $Cu^{2+} + 2LH \rightarrow CuL_2 + H^+$

Peptide copper complex may be 3N-Cu-O, Cu (Gly-L-Ala)  $H_2O$ . Specially, Cu<sup>2+</sup> ions react with cross-molecular penta glycine (Gly)<sub>s</sub>, copper-glycine complex may be formed.

Amino acid :  $Cu^{2+} + Gly^- \rightarrow Cu (Gly)^+$ ,

 $Cu (Gly)^+ + Gly^- \rightarrow Cu(Gly)_{2'}$ 

 $\textbf{Peptido: } \textbf{Cu}^{\text{2+}} + \textbf{GlyGly} \ \rightarrow \textbf{Cu} \ \textbf{(GlyGly),}$ 

Cu (GlyGly) + Gly $^ \rightarrow$  Cu(GlyGlyGly) $^-$ .

### (3) Cu<sup>2+</sup> ions induced bacteriolysis of *S. aureus* PGN cell wall by inhibition of PGN elongation through inhibitory TG/TP enzymes and PGN activated major autolysins

Bacteriolysis by balance deletion between synthesis enzyme and decomposition enzyme (autolysin) in PGN cell wall: For the sake of growth of *S. aureus* PGN cell wall, there is necessarily required for the adequate balance between PGN synthesis and PGN autolysin. When the balance is broken by Cu<sup>2+</sup> penetration, Cu<sup>2+</sup> ions are self-catalytically treated as coenzyme, that this is indicated that activation of autolysin is preceded, in which bacteriolysis and killing may result.

Copper ions inhibit PGN synthesis TG/TP against *S. aureus* that damages PGN synthetic TG/TP [25]. Cu<sup>2+</sup> ions could activate PGN autolysin, AmiA [26,27]. Hence, bacteriolysis of *S. aureus* PGN cell wall by Cu<sup>2+</sup> ions is due to inhibition of PGN elongation owing to the damages of PGN synthetic TG/TP and the activation of PGN major autolysins of AmiA.

### (4) Bacteriolysis and destruction of *E. coli* outer membrane cell wall by Cu<sup>2+</sup> ions

Inhibition of outer membrane cell wall: Cu<sup>2+</sup> ions inactivate catalyst enzyme with forming Cu<sup>+</sup> ions.

#### $Cu^{2+} + -SH \rightarrow -SCu(I) + H^{+}$

By the penetration of  $Cu^{2+}$  ions, the activations of amidase enzyme of N-terminal and endopeptidase enzyme of C-terminal are enhanced. Interaction of copper ion with *E. coli* Braun lipoprotein is considered that copper dramatically decreases the minimal inhibitory concentration of ampicillin in *E. coli* strain with a resistance mechanism relying on LD-transpeptidases (LDTs) and inhibits purified LDTs at submillimolar concentrations [28].

Accordingly, bactericidal mechanism for Cu<sup>2+</sup> ions against *S. aureus* is found that bacteriolysis and destruction of *S. aureus* cell wall occur by Cu<sup>2+</sup> ions-induced inhibition of PGN elongation through inhibitive syntheses TG/TP and PGN activated major autolysins.

The other, bactericidal mechanism for Cu<sup>2+</sup> ions against *E. coli* is found that bacteriolysis and destruction of *E. coli* cell wall occur by disruption of outer membrane structure due to degradation of lipoprotein at N-, C-terminals, damage of TG/TP enzyme and activation of PGN autolysins.

### (5) Cu<sup>2+</sup> ions-induced ROS production in *S. aureus* and *E. coli*

 $Cu^{2+}$  ions-induced reactive oxygen species (ROS)  $O_2^{-}$  and  $H_2O_2^{-}$  generated in the cell wall, and permeate into cell membrane and cytoplasm, in which in cell membrane high reactive •OH and OH<sup>-</sup> are formed by Haber-Weiss and Fenton reactions.

Haber-Weiss reaction;  $H_2O_2 + O_2 - \rightarrow \bullet OH + OH - + O_2$ 

Fenton reaction;  $Cu^+ + H_2O_2 \rightarrow \bullet OH + OH^- + Cu^{2+}$ 

Furthermore, new ROS productions occur by Fenton-like type. L=Ligand

 $LCu(II) + H_2O_2 \rightarrow LCu(I) + OOH + H^+$ 

 $LCu(I) + H_2O_2 \rightarrow LCu(II) + \cdot OH + OH^-$ 

Production of reactive oxygen species (ROS) against *S. aureus*.  $O_2^{-}$  and  $H_2O_2$  permeate into membrane and cytoplasm, that DNA molecular is damaged by oxidative stress [23]. By the penetration of copper ions into bacterial cell wall, productions of  $O_2^{-}$ ,  $H^+$ ,

 $H_2O_2$ , ONOO<sup>-</sup> occurs. The other, in *E. coli* cell wall, the productions of O<sup>-</sup>, H<sup>+</sup> in outer membrane, and  $H_2O_2$ , OH<sup>-</sup>, •OH in periplasmic space occur. These ROS and  $H_2O_2$  damage the cell membrane and the DNA molecules by oxidase stress [29].

Insight into zinc(II) ions-induced bacteriolysis function against *S. aureus* and *E. coli* 

### (1) Zinc ions-induced zinc-proteins complex formation against *S aureus*

In bacteriolysis of *S. aureus* PGN cell wall by Zn<sup>2+</sup> ions against *S. aureus*, zinc is redox-inert and has only one valence state of Zn(II). In proteins, the coordination is limited by His, Cys, Glu, and sulfur donors from the side chains of a few amino acids. In zinc sulfate solution, ZnSO<sub>4</sub> is dissociated into aqua zinc ion  $[Zn (H_2O)_6]^{2+}$  and sulfuric ion  $(S_4O_2)^-$  aqua zinc ions are liable to be bound to ligand L having negative charge. The sulfuric ion has bactericidal inactivity [30].

 $ZnSO_4 + 6H_2O \rightarrow [Zn(H_2O)_6]^{2+} + (SO_4)^{-1}$ 

 $[Zn(H_{2}O)_{6}]^{2+} + 2L^{-} \rightarrow [Zn(H_{2}O)L_{2}] + 5H_{2}O$ 

 $Zn(H_2O)L_2 \rightarrow ZnL_2 + H_2O$ 

Structural Zn<sup>2+</sup> ions are most commonly coordinated by cysteine, followed by histidine, aspartate, and glutamate that Zn-cysteine complex in bacteria, and Zn<sup>2+</sup> chelation represents a potential therapeutic approach for combating biofilm growth in a wide range of bacterial biofilm-related infections [31].

### (2) Zinc ions-induced PGN inhibitive synthesis enzymes of TG and TP against S aureus

Zinc disrupts PGN synthesis in bacterial cell wall [32] and wall teichoic acids are spatial regulators of PGN cross-linking biosynthesis TP, however, it is not explicit whether zinc ions could inhibit both TG and TP enzymes of the PGN, wherein due to uncertain relation between wall teichoic acids biosynthesis and PGN biosynthesis [33]. Metallation of PerR with Zn(II) disrupts this coordination, resulting in depression of heme synthesis but continued repression of catalase that Zn(II) intoxication leads to intracellular heme accumulation from measurement of heme content of crude extract of cells treated with zinc concentration 50 µM Zn(II) [34]. Zinc intoxication also is observed to disrupt or inhibit PGN biosynthesis [35]. The bactericidal activity of Zn<sup>2+-</sup> dependent peptidoglycan recognition proteins (PGLYRPs) is salt insensitive and requires N-glycosylation of PGLYRPs that the LD99 of PGLYRPs for Grampositive and Gram-negative bacteria is 0.3–1.7 M, and killing of bacteria by PGLYRPs does not involve permeabilization of cytoplasmic membrane, namely, zinc may be shown to inhibit

PGN biosynthesis TG [36]. But, these limited PGLYRPs don't be applicable for Gram-negative bacteria. Thus, zinc ions could inhibit PGN synthesis TG against *S. aureus*.

## (3) Zinc ions-induced PGN inhibitive elongation due to inhibitory TG enzyme and activation of autolysin against *S aureus*

Zn<sup>2+</sup> binding Rv3717 showed no activity on polymerized PGN and however, it is induced to a potential role of N-Acetylmuramyl L-alanine Amidase [37], PGN murein hydrolase activity and generalized autolysis; Amidase MurA [38], Lytic Amidase LytA [39], enzymatically active domain of autolysin LytM [40], Zinc-dependent metalloenzyme AmiE [41] as prevention of the pathogen growth, and Lysostaphin-like PGN hydrolase and glycylglycine endopeptidase LytM [42]. Zn<sup>2+</sup> ions-induced bacteriolysis and destruction of *S. aureus* PGN cell wall could be enhanced by the inhibitions of PGN elongation simultaneously with the activations of these PGN autolysins. Thus, zinc(II) ions can impair the activity of PGN biosynthesis TG and PGN elongation by bacteriolytic destruction of bacterial cell walls, causing bacterial lysis [43].

Accordingly, zinc induced PGN inhibitory synthesis corresponds to disruption of bacterial cell wall, but zinc ions may be possible to inhibit PGN synthesis TG and PGN elongation by PGN activated major autolysin of amidase against *S. aureus*.

## (4) Zinc ions-induced disruptive outer membrane structure by hydrolases of lipoproteins at C-, N-terminals against *E. coli*

In zinc ion uptake across the outer membrane, the lipoproteins of Omp A, Omp C, Omp F porins have a role for at least some of these proteins in Zn<sup>2+</sup> uptake, in which the lipoproteins have metallic cation selective and hydrophilic membrane crossing pore, to be effective for zinc transfer [43]. Zinc (II) ions react with -SH base, and then H2 generates. Zinc bivalent is unchangeable as -SZn—S— bond 4-coordinated.

#### $Zn^{2+} + 2(-SH) \rightarrow -SZn(II) - S- + 2H^+$

ZnPT (zinc pyrithione) and Tol (Tol proteins)-Pal (Protein associated lipoprotein) complex are antimicrobial agents widely used, however, it has recently been demonstrated to be essential for bacterial survival and pathogenesis that outer membrane structure may be disrupted [45,46]. Interaction zinc ions with *E. coli* Braun lipoprotein may be considered that

Lpp as a new target of antimicrobial peptides is Gram-negative bacterial cell surface receptor for cationic antimicrobial peptides [47].

# (5) Zinc ions-induced PGN inhibitive elongation through the damage of PGN synthesis enzyme of zinc-protein in periplasmic space and the activation of PGN autolysins against *E. coli*

The zinc-induced decrease of protein biosynthesis led to a partial disappearance of connexin-43 of protein synthesis in neurons [48], but it is unknown whether PGN synthesis is inhibited. Further, it is also unclear whether the both TG/TP should be inhibited by the zinc ions [49-51]. The other, zinc ions were accumulated in E. coli periplasmic space, in which the zinc ions are spent to the activation of bacteriolysis of the cell wall. Zinc depending PGN autolysin, amidase PGRPs [52], zinc metallo enzymes AmiD [53], zinc-containing amidase; AmpD [54], zinc-present PGLYRPs [55] serve to be effective for the PGN autolysins. It is particularly worth noting that enhancement of the activities of autolysins is characterized on PGN carboxypeptidase-transpeptidase IIW [23] requiring divalent cations. Thus, the inhibition of PGN elongation had been occurred by zinc ion-induced activa tions of PGN hydrolases and autolysins.

Accordingly, bactericidal mechanism for Zn<sup>2+</sup> ions against *E. coli* is found that bacteriolysis and destruction of *E. coli* cell wall occur by disruption of outer membrane structure due to degrading of lipoprotein at C-, N-terminals and PGN formation inhibition through PGN inhibitive synthesis TG and PGN activated autolysins of *amidase* and *carboxypeptidase*transpeptidase.

### (6) Zinc ion-induced ROS generation against *S. aureus* and *E. coli*

**Zinc induced production of reactive oxygen species (ROS) against S. aureus:**  $O_2^-$  and  $H_2O_2$  permeate into membrane and cytoplasm, that DNA molecular is damaged by oxidative stress [23]. For the penetration of zinc ions to PGN cell wall, the ROS production such as superoxide anion radical  $O_2^-$ , hydroxyl radical •OH, hydrogen peroxide  $H_2O_2$  occurred from superoxide radical  $O_2^-$  molecular [56].  $O_2^-$  and and  $H_2O_2$ permeate into membrane and cytoplasm, and then, DNA molecular is damaged by oxidative stress [57].

$$O_{2} + e^{-} + H^{+} \rightarrow \bullet HO_{2}$$

$$\bullet HO_{2} \rightarrow H^{+} + O_{2}$$

$$H_{2}O_{2} + e^{-} \rightarrow HO^{-} + \bullet OH$$

$$2H^{+} + \bullet O_{2}^{-} + \bullet O_{2}^{-} \rightarrow H_{2}O_{2} + O_{2}$$

$$H_{2}O \rightarrow \bullet OH + \bullet H + e^{-} \rightarrow H_{2}O_{3}$$

**Zinc induced ROS production and oxidative stress against E. coli:** Zinc ions react with -SH, and H+, ROS generate. In *E. coli*,

free radicals ( $O_2^-$ ,  $OH^+$ , •OH) and  $H_2O_2$  are formed as follows [58]:

$$O_2 + e \rightarrow O_2^ 2O_2^- + 2H^+ \rightarrow H_2O_2 + O_2^-$$
  
 $O_2^- + H_2O_2 \rightarrow OH^- + \cdot OH + O_2^-$ 

In the cell wall, reacting with polyunsaturated fatty acids:

LH + OH• 
$$\rightarrow$$
 L• + HOH  
L• + 0<sub>2</sub>  $\rightarrow$  LOO•

#### $\mathbf{LH} + \mathbf{LOO}\bullet \rightarrow \mathbf{L}\bullet + \mathbf{LOOH}$

Zinc-containing Peptidoglycan Recognition Proteins (PGRPs) induce ROS production of  $H_2O_2$ , O<sup>-</sup>, HO•, the ROS occur the oxidative stress, and killing by stress damage [59].

Accordingly, as mentioned above, metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions-induced PGN inhibitive synthesis TG/TP, distruptive OM lipoptotein, and PGN activated autolysin against *S. aureus* and *E. coli* cell walls are summarized in Table 2, in which are included in bacteriolytic mechanisms for complete-ionized metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions.

**Table 2:** Metallic Ag+, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions-induced PGN inhibitive synthesis TG/TP, disruptive OM lipoprotein, and PGN activated autolysin against *S.aureus* and *E.coli* cell walls.

	<b>Bacteriolytic mechanism against</b> <i>S. aureus</i> ; Bacteriolysis and destruction of <i>S. aureus</i> cell wall by metallic $Ag^+$ , $Cu^{2+}$ , $Zn^{2+}$ ions-induced PGN elongation inhibition through PGN inhibitory TG/TP (TG for $Zn^{2+}$ ion) and PGN activated major autolysins.		<b>Bateriolytic mechanism against</b> <i>E. coli</i> ; Metallic $Ag^+$ , $Cu^{2+}$ , $Zn^{2+}$ ions can disrupt OM lipoptiotein and inhibit PGN elongation through PGN inhibitory TG/TP (TG for Zn <sup>2+</sup> ion) and PGN activated major autolysins against <i>E. coli</i> .		

#### CONCLUSIONS

Insights into metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions respectively induced bacteriolyses and destructions of bacterial cell walls are performed, subsequently, metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions-induced bacteriolytic mechanisms are clarified against *S. aureus* and *E. coli*.

Bacteriolytic and destructive mechanism for Ag<sup>+</sup> ions solution is clarified that bacteriolysis and destruction of bacterial cell wall occur by the disruption of *E. coli* outer membrane structure owing to the activation of *Endopeptidase* (*L,D-transpeptidase, LdtF*) of lipoprotein at C- and N-terminals, and by inhibition of PGN elongation through the inactivation of PGN synthetic TG/TP enzymes and the activation of PGN major autolysins of amidase, peptidase, and carboxypeptidase against *S. aureus* and *E. coli*.

Bacteriolysis of *S. aureus* PGN cell wall by Cu<sup>2+</sup> ions is thought to be due to inhibition of PGN elongation owing to the damages of PGN both synthetic TG/TP and the activations of PGN major autolysin of AmiA. The other, bacteriolysis of *E. coli* cell wall by Cu<sup>2+</sup> ions occurs by disruption of outer membrane structure due to degradation of lipoprotein at N-,C-terminals, damage of PGN syntheses TG and TP enzyme, and activations of PGN major autolysins. Furthermore, deletion of PGN autolysin also becomes bacteriolytic factor. Anti-bacterial activity of Zn<sup>2+</sup> ions against *S. aureus* has been found that Zn<sup>2+</sup> ions-induced PGN autolysin activation could be enhanced the inhibitions of PGN elongation simultaneously, with bacteriolysis and destruction of *S. aureus* PGN cell wall.

The activations of these PGN autolysins by Zn<sup>2+</sup> ions could be enhanced the inhibitions of PGN elongation simultaneously, with bacteriolysis of *S. aureus* PGN cell wall. The other, antibacterial mechanism of Zn<sup>2+</sup> ions against *E. coli* was found that Bacteriolysis and destruction of *E. coli* cell wall by Zn<sup>2+</sup> ions are due to disruption of outer membrane structure by degrading of lipoprotein at C-, N-terminals, owing to PGN formation inhibition by damage of PGN synthesis TG and PGN autolysins of amidase and carboxypeptidase-transpeptidase.

Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions-induced ROS generation of O<sub>2</sub><sup>-</sup> and H<sub>2</sub>O<sub>2</sub> and ROS-mediated oxidative stress in bacterial cell lead to killing by stress damage for silver ions, cell membrane damages due to high reactive •OH and OH<sup>-</sup> are formed by Haber-Weiss and Fenton reactions for Cu<sup>2+</sup> ions, and DNA molecular damage for Zn<sup>2+</sup> ions.

Accordingly, bactericidal mechanism for complete-ionized metallic Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions solutions has been established that Ag<sup>+</sup>, Cu<sup>2+</sup>, Zn<sup>2+</sup> ions, respectively, induced the bacteriolyses and destructions of bacterial cell walls occur by disruption of *E. coli* outer- membrane lipoprotein and by inhibition of PGN elongation through PGN both inactive syntheses TG/TP (TG
